

Epic 1: Data Collection

Story 1: Dataset Collection and Loading

The first phase of the AI Flood Prediction System involves collecting a reliable flood prediction dataset containing weather and environmental parameters. The dataset includes important features such as **Temperature, Humidity, Cloud Cover, Annual Rainfall**, and other meteorological variables that influence flood occurrence.

The dataset is loaded into the Jupyter Notebook/Python environment using the **Pandas** library for further analysis and preprocessing. After loading, the dataset is inspected to understand its structure, number of records, data types, and feature distributions. This step ensures that the data is complete and suitable for machine learning model development.

The collected dataset serves as the foundation for data visualization, preprocessing, model training, evaluation, and deployment of the flood prediction system.

Outcome:

- Successfully collected the flood prediction dataset.
- Loaded the dataset into the Python environment using Pandas.
- Verified dataset structure and feature availability.
- Prepared the dataset for the next phase of analysis and preprocessing.
